INTRODUCTION

Presently, the region of coordination polymers has undergone much development, for the purpose of designing new materials with remarkable physical properties. Many one-, two- and three-dimensional structures have been synthesized and characterized [1-3]. The amine salts of halogen complexes were prepared and these compounds are interesting because they exhibit phase transitions related to motion of the ammonium cations. Recently, investigation on organic-inorganic polar crystals has become very important, because of its quadratic nonlinear optical properties [4,5]. Metal complexes find position in the fields of biological catalysis and functions, such as in metabolism [6,7]. Complexes of cobalt are useful for nutritional supplementation to deliver cobalt in a form, which effectively raises the bioavailability, for instance, vitamin B12 by microorganisms present in the gut. Mixed ligands cobalt complexes find potential applications in the fields of antitumour, antibacterial, antimicrobial, radio-sensitization and cytotoxicity activities [12-15].

The growth of crystals containing two or more components plays an important role in several modern industrial applications [16]. The art of growing crystals has always been fascinating and challenging. Modern technology employing semiconductors, magnetic garnets, ultraviolet and infrared solid state lasers, requires materials in good crystalline form. Solid state electronics has become the key to modern technology and its importance is likely to keep growing [17]. Extensive studies have been carried out on the preparation, growth and characterization of A2BX4 type compounds, where A = univalent cations like Na+, K+, NH4+, Rb+ and its alkyl derivatives; B = divalent transition metal cations like Fe2+, Co2+, Ni2+, Mn2+, etc. and X= halogen (Cl, Br and I ). A2BX4 compounds represent the largest known groups of insulating crystals with structurally

gically found in most tissues. Complexes of cobalt are useful for nutritional supplementation to deliver cobalt in a form, which effectively raises the bioavailability, for instance, vitamin B12 by microorganisms present in the gut. Mixed ligands cobalt complexes find potential applications in the fields of antitumour, antibacterial, antimicrobial, radio-sensitization and cytotoxicity activities [12-15].

The growth of crystals containing two or more components plays an important role in several modern industrial applications [16]. The art of growing crystals has always been fascinating and challenging. Modern technology employing semiconductors, magnetic garnets, ultraviolet and infrared solid state lasers, requires materials in good crystalline form. Solid state electronics has become the key to modern technology and its importance is likely to keep growing [17]. Extensive studies have been carried out on the preparation, growth and characterization of A2BX4 type compounds, where A = univalent cations like Na+, K+, NH4+, Rb+ and its alkyl derivatives; B = divalent transition metal cations like Fe2+, Co2+, Ni2+, Mn2+, etc. and X= halogen (Cl, Br and I ). A2BX4 compounds represent the largest known groups of insulating crystals with structurally
in commensurate phases. In their normal parent phase, they are orthorhombic and pseudo hexagonal, with space group pccm and have the structure of $\beta$-K$_2$SeO$_4$ type [18]. Typically on decreasing temperature they undergo a second order phase transition at $T_i$ (in commensurate transition temperature) to a one dimensionally modulated in commensurate (IC) phase with the in commensurate wave vector directed along the pseudo hexagonal 'a' axis. The occurrence of in commensurate phases in these crystals was interesting. As the temperature is lowered a variety of phase transitions are observed. A comprehensive list of the relevant A$_2$BX$_4$ materials and a review of their properties has been reported by Cummins [19]. In this view, we have prepared PTMATCL-Co(II) compound and characterized through elemental analysis, FTIR, TG-DTA, DSC and $^1$H NMR spectroscopy.

**EXPERIMENTAL**

**Preparation and crystal growth:** Crystals of phenyl trimethylammonium pentachlorocobaltate(II)-alkyl halometallate were grown by slow evaporation method at room temperature (Scheme-I). Aqueous solutions of Analar grade (E. Merck) phenyl trimethylammonium chloride and cobaltous chloride were prepared separately in 2:1 molar ratio using triple distilled water. The two solutions were mixed thoroughly. In order to maintain acidic medium and to avoid hydrolysis 1 mL of HCl is added. The resulting solution was filtered and the collected filtrate in the beaker was covered by filter paper with minute pores for growing crystals. Care was taken to minimize the temperature gradient and mechanical shock. The PTMATCL-Co(II) crystals obtained by slow evaporation method at room temperature after 15 days were bright, blue colour and transparent (Fig. 1). The grown crystals of phenyl trimethylammonium-pentachlorocobaltate(II) were characterized through elemental analysis, NMR spectroscopy, powder X-ray diffraction and thermal analysis.

$$2\text{C}_6\text{H}_5\text{(CH}_3\text{)}_3\text{NCl} + \text{CoCl}_2 \xrightarrow{\text{H}_2\text{O}/\text{HCl}} [\text{C}_6\text{H}_5\text{(CH}_3\text{)}_3\text{N}]_2\text{CoCl}_4$$

**Scheme-I:** Reaction of phenyl trimethylammonium tetrachlorocobaltate

---

**RESULTS AND DISCUSSION**

**Elemental analysis:** The results of elemental analysis (C, H and N) of phenyl trimethylammonium pentachlorocobaltate (II) crystals is shown in Table-1. The experimental values of carbon, hydrogen and nitrogen are very close to the theoretical values based on A$_2$BX$_4$ formula. The elemental analysis thus confirmed the stoichiometry of [PTMATCL-Co(II)] compound.

**FT-IR studies:** Various absorption frequencies and the assignments of PTMATCL-Co(II) are presented in Table-2. The peak is observed at 3386.04 cm$^{-1}$ due to N-H stretching of ammonium ion. The peak at 3030.36 cm$^{-1}$ is due to Ar-H stretching vibrations of phenyl group. Bending deformation mode of methyl scissoring is seen at 1491.20 cm$^{-1}$. Peak at 1465.56 cm$^{-1}$ is due to bending deformation mode of methyl group. The peak at 998.69 cm$^{-1}$ is due to C-H out of plane bending vibration. The peak at 767.59 cm$^{-1}$ is due to methyl in-plane bending vibration, mono-substituted aromatic ring stretching. C-N-C and C-C-N deformation modes, disubstituted meta C-H deformation are seen at 690.84 cm$^{-1}$. The peak is observed at 552.90 cm$^{-1}$ is due to greater electronegativity in C-Cl atom.

**$^1$H NMR studies:** $^1$H NMR spectrum of PTMACL-Co(II) is shown in Fig. 2. In this spectrum, two signals are observed at different $\delta$ values for methyl and Ar-H groups present in the compound. All the methyl and Ar-H groups are in the same environment. The expected $\delta$ values for methyl and aromatic protons are 1.2 to 1.4 ppm and 7.5 to 7.8 ppm, respectively. In this spectrum higher $\delta$ value is obtained. This is due to the deshielding effect which confirms the presence of positive charge on nitrogen containing three methyl groups and Ar-H groups. The signal at 3.4 $\delta$ is due to the presence of methyl group protons. The intensity of the peak is higher due to methyl proton. Peak at 7.5 $\delta$ is due to Ar-H protons. The higher $\delta$ value is due to deshielding effect because of electropositive nitrogen adjacent to...
to it. The deshielding effect decreases as the distance between the methyl protons and the electropositive nitrogen increases. As the distance increases, there is diminishing deshielding effect. The spectrum endorses the presence of methyl and phenyl protons, confirming the existence of trimethyl groups in the compound.

**TG-DTA studies:** TG-DTA thermogram of compound phenyl trimethylammonium pentachlorocobaltate(II) (Fig. 3). The compound is subjected to uniform heating of 20 °C/min in nitrogen atmosphere. The TG-DTA curve showed a four stage weight loss when heated between the room temperature and 800 °C. The first stage decomposition started at 10 °C and ended at 180 °C. There is a weight loss of 6.53 % which can be accomplished by formulating the following decomposition reaction of the compound. When the compound undergoes decomposition as above, one mole of compound decomposes into one mole of phenyl trimethylammonium tetrachlorocobaltate(II) \([\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]_2\text{CoCl}_4\) and one mole of chlorine. Since \([\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]_2\text{CoCl}_4\) is stable at these temperature it does not vaporized at these temperature. Theoretical loss of 6.97 % is observed whereas the experimental loss observed is 6.53 %. The difference is 0.44 % which indicated the experimental and theoretical values are close to each other and within experimental error.

In the second stage, we have only one mole of phenyl trimethylammoniumtetrachlorocobaltate(II) \([\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]_2\text{CoCl}_4\) at 200 °C. When the temperature is increased there is decomposition of \([\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]_2\text{CoCl}_4\) from 200 to 278 °C with a weight loss of 33.80 %. This weight loss can be accounted for by formulating the following reaction:

\[
\text{33.80 % } [\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]\text{CoCl}_3 + \text{C}_6\text{H}_5(\text{CH}_3)_3\text{NCl} \rightarrow [\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]_2\text{CoCl}_4
\]

The experimental weight loss is 33.80 % while the theoretical weight loss is 33.77 %. The difference is only 0.03 % which is again within the error limit. In the third stage, we have only \([\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]_2\text{CoCl}_4\). As the temperature increases, there is decomposition of \([\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]_2\text{CoCl}_4\) from 278 °C to 700 °C with a weight loss of 44.90 %. Thus weight loss can be accounted for by formulating the following decomposition reaction:

\[
\text{44.90 % } \text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}\text{CoCl} + \text{Cl}_2 \rightarrow [\text{C}_6\text{H}_5(\text{CH}_3)_3\text{N}]\text{CoCl}_3
\]

Theoretical loss of weight of leads to the loss of 44.90 % whereas the experimental loss observed is 45.29 %. The difference is only 0.39 % indicating that the result is within experimental error. The theoretical value of residual mass is about 14.77 %, whereas the experimental value of residual mass is 13.94 %. The difference is found to be 0.83 % only indicating that the experimental and theoretical values are very close to each other and within experimental error. Thus the compound decomposes in three stages. The decomposition starts at 10 °C and gets completed at 700 °C. Thus, the thermogram confirmed the stoichiometry of compound which is evident from the decomposition patterns.

**X-ray crystallographic studies:** Intensity data collection was done in a Bruker axs kappa Apex II single crystal X-ray diffractometer equipped with graphite monochromated Mo(Kα) (λ = 0.7107 Å) radiation [20] and CCD detector, using good quality crystals of PTMATCL-Co(II) with the dimensions 0.10 mm × 0.20 mm × 0.20 mm. The unit cell parameters were determined from 36 frames (0.5º phi-scan) measured from three different crystallographic zones and using the method of difference vectors. The intensity data were collected with an average four-fold redundancy per reflection and optimum resolution (0.75 Å). The intensity data collections were processed by applying Lorentz & polarization (Lp) correction and decay correction by using the program SAINT-NT (version 6.0). Empirical absorption correction (multi-scan) was performed using SADABS program [21]. The structures were solved by direct methods using the program SHELXS97 [22] and refined on F² by full-matrix least-squares procedures using the program SHELXL97 [23]. The non-hydrogen atoms were refined anisotropically and the hydrogen atoms in both the structures were constrained to ride on their respective parent atoms. The geometrical parameters were calculated using the programs PARST [24] and PLATON [25].

**X-ray diffraction studies:** Three dimensional structure of the titled compound was obtained from single crystal X-ray diffraction studies. The ORTEP diagram for PTMATCL-Co(II)
compound is shown in Fig. 4 and the displacement ellipsoids were drawn at 50% probability level. The molecule composes of two anilinium moiety and a tetrachlorocobaltate moiety. The cell parameters were $a = 15.5329(4)$ Å, $b = 9.5793(4)$ Å, $c = 30.8443(8)$ Å and $\beta = 95.450(2)^\circ$. It belongs to monoclinic crystal system with $C2/c$ space group. The crystal data of PTMATCL-Co(II) molecule is presented in Table-3. Table-4 depicted the atomic coordinates and its equivalent isotropic displacement parameters for non-hydrogen atoms of PTMATCL-Co(II).

The phenyl rings of both anilinium group were existing in the planar geometry. The C-C distances among the benzene ring of both phenyl trimethylammonium moiety is in agreement with the literature values [26] (Table-5). The dihedral angle between two phenyl trimethyl ammonium moieties was found to be 89.49(16)°. The hydrogen bond lengths were in the range of 0.9300 Å to 0.9600 Å. The sum of bond angles around N1[328.6(12)°] and N2[330.7(6)°] of two phenyl trimethyl-ammonium moieties was in accordance with sp³ hybridization [27]. The torsion angles of PTMATCL-Co(II) compound are given in Table-6. The tetrachlorocobaltate group exhibited distorted tetrahedral geometry with Co(II) ion surrounded by four Cl atoms, Cl-Co-Cl angles ranging from 107.16(3)° and 112.12(3)°. The Co-Cl bond lengths are in the range of 2.2653(7) Å and 2.2798(8) Å, which were close to those observed in related literature [28]. In general, metal-halogen bonds are weaker and association. Here, two chlorine atoms Cl1 and Cl3 acts as acceptors via C-H···Cl H-bonds. The remaining chlorine atoms Cl2 and Cl4 bond lengths were in the range of 2.2654(7) Å and 2.2798(8) Å, which were close to those observed in related literature [28]. In general, metal-halogen bonds are weaker and have higher bond lengths [29]. The Co-Cl bond lengths are larger, when matched with C-N and C-C bond lengths (Table-5).

In PTMATCL-Co(II) compound, C-H···Cl type of hydrogen bonding plays an important role in creating the molecular association. Here, two chlorine atoms Cl1 and Cl3 acts as acceptors of C-H···Cl H-bonds. The remaining chlorine atoms Cl2 and Cl4 do not contribute in hydrogen bonding network with the van der Waals forces. The deviation from the perfect tetrahedral arrangement around Co(II) in PTMATCL-Co(II) molecule can be described by participation of chlorine ions in the hydrogen bonding. The Cl1 atom behaves as an acceptor for the methyl group hydrogen’s from the neighbouring molecule via

C16-H16B---C1 and C17-H17C---C1 interactions, forming a loop (Fig. 5, Table-7). The trifurcation of chlorine atom Cl1 was done at (-x,y,-z+3/2) via C9-H9B---Cl1 hydrogen bond. The C17-H17A---C1 intermolecular interaction also contributes to the crystal packing, which forms zig-zag chains along a-axis.

### Conclusion

Alkyl halometallate crystals of phenyl trimethyl ammonium pentachlorocobaltate(II) [PTMATCL-Co(II)] was grown by slow evaporation method at room temperature. The spectral studies of FTIR, 1H spectra and the elemental analysis to confirm the stoichiometry of the compound were obtained which is in agreement with the three dimensional crystal structure derived from the single crystal X-ray studies. The crystal data and cell parameters evidently showed that the compound belongs to monoclinic crystal system with C2/c space group. In thermal studies, the mass change of the system is measured as the function of temperature which shows PTMATCL-Co(II) molecule with stands up to 200 ºC elucidating its good melting point. Overall, the compound phenyl trimethylammonium pentachlorocobaltate(II) was synthesized and crystallized to progress the modern industrial applications of alkyl halometallates with its good thermal stability.
